

Even with oracle static analysis, real cross-iteration output dependences (29->29, 43->29, 13->13) inhibit parallelization.

To enable parallelization, the underlying memory objects of these accesses should be privatizable (required property).

Privatizability criteria for a memory object:

- i) identification of all accesses of this object within the loop
- ii) absence of cross-iteration flow dependences on each of these accesses
